

Direct Seeding – The Complete Guide

Seed management.

Direct seeding is not suitable for zucchinis, bulb onions, egg plants, melone, tomatoes, pepper and cucumber. It is suitable for carrots, beets, spinach, lettuce, peas and corn.

Similarly, make rows and put in seeds directly as plant need certain temperatures to germinate and grow. Don't seed crops before winter hits for a mid summer harvest and seed crops at optimal depth as proper depth is key in allowing each and every crop the chance to maximise its growth habit for roots and shoots.

Proper spacing should be done right from start and prepare seed bed well and make ditches of desired rows and depth. Sow the seed in the trench, cover them with soil and add loose mulch to the bed for protection and then water.

Furthermore for surface method, put a thin layer of organic soil on the seedbed of 3 inches wide to desired row length and spread seeds on soil and cover with skin coat of potting mix, mulch and water thoroughly. For multiseeding, method, clear bed and make trenches of 2 inches deep and place 2 seeds per 6 inches apart in the trench of 2 inches deep.

Finally, cover with organic mix, mulch and water.
